

Accessing Databases with SQL Magic

Estimated time needed: **15** minutes

Objectives

After completing this lab you will be able to:

- Perform simplified database access using SQL "magic"

To communicate with SQL Databases from within a JupyterLab notebook, we can use the SQL "magic" provided by the [ipython-sql](#) extension. "Magic" is JupyterLab's term for special commands that start with "%". Below, we'll use the *load_ext* magic to load the ipython-sql extension. In the lab environment provided in the course the ipython-sql extension is already installed and so is the `ibm_db_sa` driver.

```
%load_ext sql
```

Here you will be creating and connecting to a new SQLite database SQLiteMagic.

The syntax for connecting to magic sql using sqlite is

%sql sqlite://DatabaseName

where DatabaseName will be your **.db** file

```
import csv, sqlite3

con = sqlite3.connect("SQLiteMagic.db")
cur = con.cursor()

%load_ext sql

%sql sqlite:///SQLiteMagic.db
```

For convenience, we can use %%sql (two %'s instead of one) at the top of a cell to indicate we want the entire cell to be treated as SQL. Let's use this to create a table and fill it with some test data for experimenting.

```
%%sql

CREATE TABLE INTERNATIONAL_STUDENT_TEST_SCORES (
    country VARCHAR(50),
    first_name VARCHAR(50),
    last_name VARCHAR(50),
    test_score INT
);
INSERT INTO INTERNATIONAL_STUDENT_TEST_SCORES (country, first_name,
last_name, test_score)
```

VALUES

```
('United States', 'Marshall', 'Bernadot', 54),
('Ghana', 'Celinda', 'Malkin', 51),
('Ukraine', 'Guillermo', 'Furze', 53),
('Greece', 'Aharon', 'Tunnow', 48),

('Venezuela', 'Ron', 'Leggitt', 60),
('Russia', 'Flint', 'Gokes', 40),
('China', 'Linnet', 'Conelly', 52),

```
('Philippines', 'Nikolas', 'Birtwell', 57),  
( 'Australia', 'Eduard', 'Leipelt', 53)
```

Using Python Variables in your SQL Statements

You can use python variables in your SQL statements by adding a ":" prefix to your python variable names.

For example, if I have a python variable `country` with a value of `"Canada"`, I can use this variable in a SQL query to find all the rows of students from Canada.

```
country = "Canada"  
%sql select * from INTERNATIONAL_STUDENT_TEST_SCORES where country  
= :country
```

Assigning the Results of Queries to Python Variables

You can use the normal python assignment syntax to assign the results of your queries to python variables.

For example, I have a SQL query to retrieve the distribution of test scores (i.e. how many students got each score). I can assign the result of this query to the variable `test_score_distribution` using the `=` operator.

```
test_score_distribution = %sql SELECT test_score as "Test_Score",  
count(*) as "Frequency" from INTERNATIONAL_STUDENT_TEST_SCORES GROUP  
BY test_score;  
test_score_distribution
```

Converting Query Results to DataFrames

You can easily convert a SQL query result to a pandas dataframe using the `DataFrame()` method. Dataframe objects are much more versatile than SQL query result objects. For example, we can easily graph our test score distribution after converting to a dataframe.

```
dataframe = test_score_distribution.DataFrame()  
  
%matplotlib inline  
# uncomment the following line if you get an module error saying  
# seaborn not found  
# !pip install seaborn==0.9.0  
import seaborn  
  
plot = seaborn.barplot(x='Test_Score',y='Frequency', data=dataframe)
```

Now you know how to work within JupyterLab notebooks using SQL "magic"!

```
%%sql  
  
-- Feel free to experiment with the data set provided in this notebook  
for practice:
```

```
SELECT country, first_name, last_name, test_score FROM  
INTERNATIONAL_STUDENT_TEST_SCORES;
```
